

# CPE/EE 695: Applied Machine Learning

## *Lecture 10: Genetic Algorithms*

Dr. Shucheng Yu, Associate Professor  
Department of Electrical and Computer Engineering  
Stevens Institute of Technology

# Evolution in Biology

Organisms (animals or plants) produce a number of offspring which are almost, but not entirely, like themselves

Variation may be due to **mutation** (random changes)

Variation may be due to **reproduction** (offspring have some characteristics from each parent)

Some of these offspring may survive to produce offspring of their own—some won’t

The “better adapted” offspring are more likely to survive

Over time, later generations become better and better adapted

**Genetic algorithms** use this same process to “evolve” better programs

# Genetic Algorithms

## Population of individuals

Individual is feasible solution to problem

Each individual is characterized by a **Fitness function**

Higher fitness is better solution

Based on their fitness, parents are selected to reproduce **offspring** for a new **generation**

Fitter individuals have more chance to reproduce

New generation has same size as old generation; old generation dies

Offspring has **combination** of properties of two parents

If well designed, population will **converge** to optimal solution

## GA(*Fitness*, *Fitness\_threshold*, *p*, *r*, *m*)

*Fitness*: A function that assigns an evaluation score, given a hypothesis.

*Fitness\_threshold*: A threshold specifying the termination criterion.

*p*: The number of hypotheses to be included in the population.

*r*: The fraction of the population to be replaced by Crossover at each step.

*m*: The mutation rate.

- Initialize population:  $P \leftarrow$  Generate *p* hypotheses at random
- Evaluate: For each  $h$  in  $P$ , compute  $\text{Fitness}(h)$
- While  $[\max_h \text{Fitness}(h)] < \text{Fitness\_threshold}$  do

Create a new generation,  $P_s$ :

1. Select: Probabilistically select  $(1 - r)p$  members of  $P$  to add to  $P_s$ . The probability  $\Pr(h_i)$  of selecting hypothesis  $h_i$  from  $P$  is given by

$$\Pr(h_i) = \frac{\text{Fitness}(h_i)}{\sum_{j=1}^p \text{Fitness}(h_j)}$$

2. Crossover: Probabilistically select  $\frac{r \cdot p}{2}$  pairs of hypotheses from  $P$ , according to  $\Pr(h_i)$  given above. For each pair,  $\langle h_1, h_2 \rangle$ , produce two offspring by applying the Crossover operator. Add all offspring to  $P_s$ .
  3. Mutate: Choose *m* percent of the members of  $P_s$  with uniform probability. For each, invert one randomly selected bit in its representation.
  4. Update:  $P \leftarrow P_s$ .
  5. Evaluate: for each  $h$  in  $P$ , compute  $\text{Fitness}(h)$
- Return the hypothesis from  $P$  that has the highest fitness.

# Basic principles 1

## Coding or Representation

String with all parameters

## Fitness function

Parent selection

## Reproduction

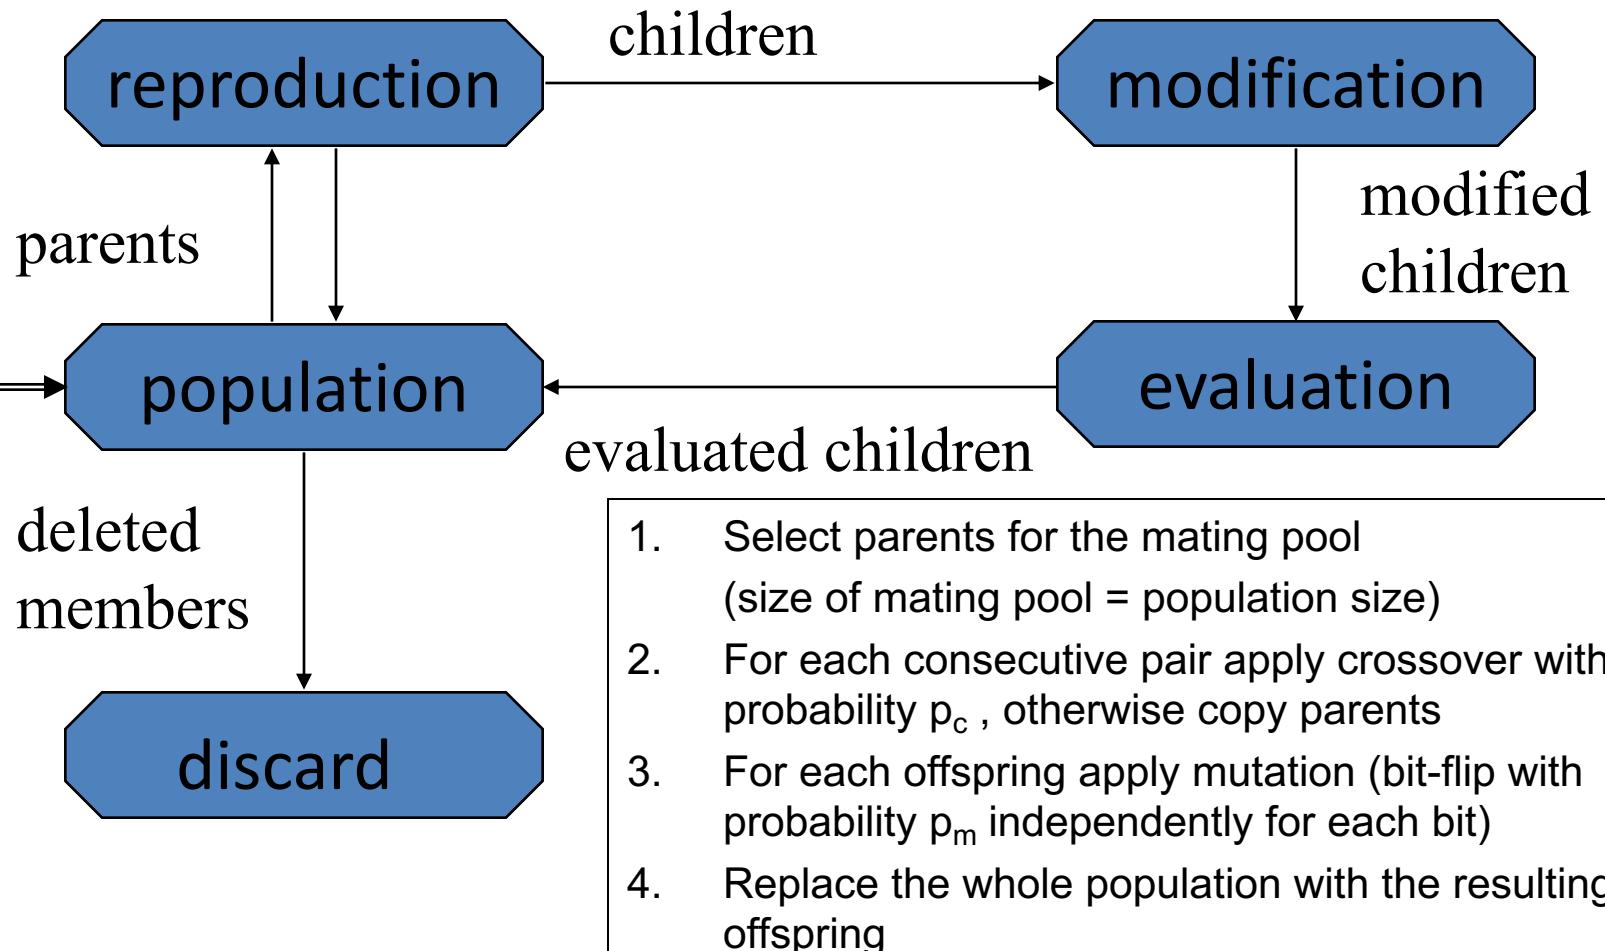

Crossover

Mutation

## Convergence

When to stop

# The GA Cycle of Reproduction

# Coding

Parameters of the solution (**genes**) are concatenated to form a string (**chromosome**)

All kind of **alphabets** can be used for a chromosome (numbers, characters),

Bit strings (0101 ... 1100)

Real numbers (43.2 -33.1 ... 0.0 89.2)

Permutations of element (E11 E3 E7 ... E1 E15)

Lists of rules (R1 R2 R3 ... R22 R23)

Program elements (genetic programming)

... any data structure ...

**Order** of genes on chromosome can be important

Generally many **different codings** for the parameters of a solution are possible

# Reproduction Operators

## Crossover

Two parents produce two offspring

There is a chance that the chromosomes of the two parents are copied unmodified as offspring

There is a chance that the chromosomes of the two parents are randomly recombined (crossover) to form offspring

Generally the chance of crossover is between 0.6 and 1.0

## Mutation

There is a chance that a gene of a child is changed randomly

Generally the chance of mutation is low (e.g. 0.001)

# Reproduction Operators -- Crossover

## Crossover

Generating offspring from two selected parents

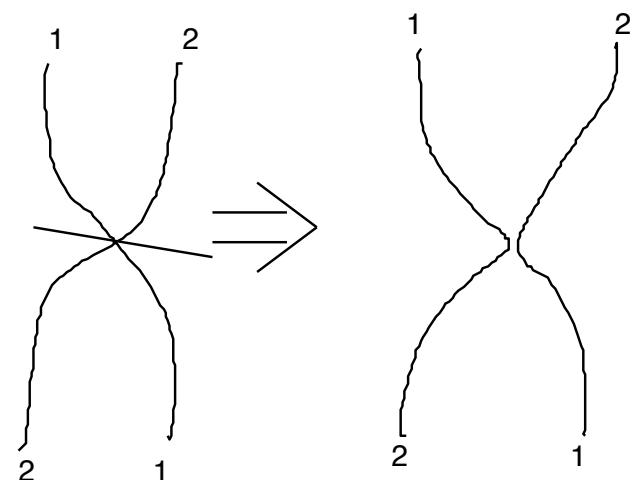

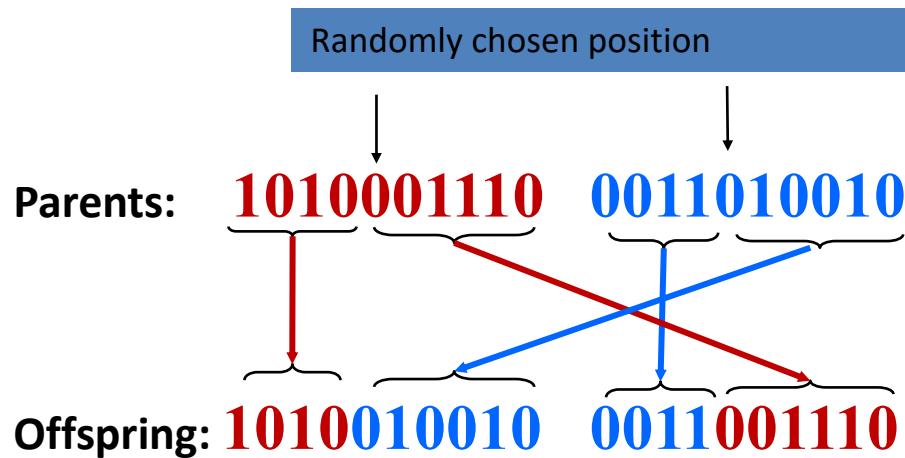

Single point crossover

Two point crossover (Multi point crossover)

Uniform crossover

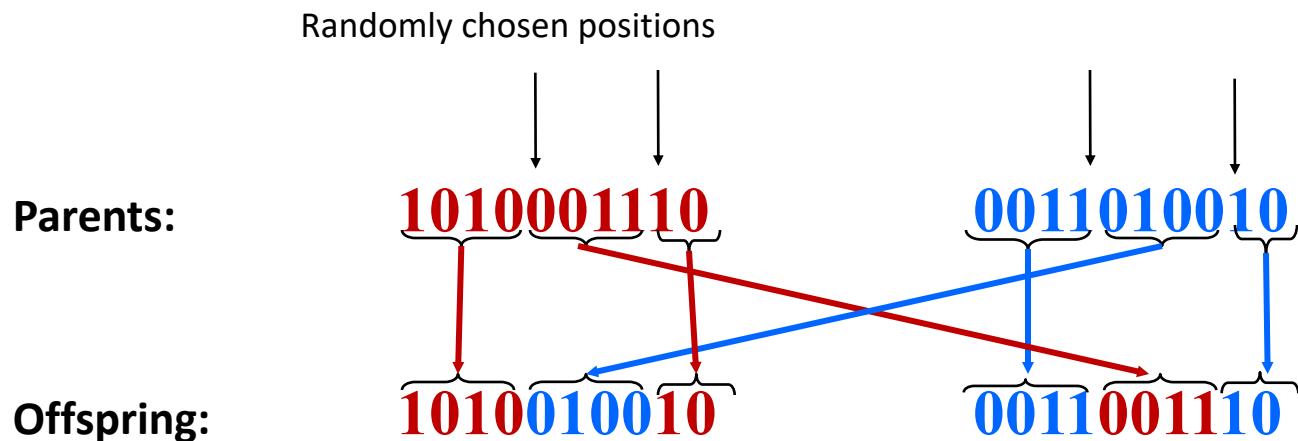

# One-point crossover

- Randomly one position in the chromosomes is chosen
- Child 1 is head of chromosome of parent 1 with tail of chromosome of parent 2
- Child 2 is head of 2 with tail of 1

# Two-point crossover

- Two positions in the chromosomes are chosen randomly
- Avoids that genes at the head and genes at the tail of a chromosome are always split when recombined

# Uniform crossover

A random mask is generated

The mask determines which bits are copied from one parent and which from the other parent

Bit density in mask determines how much material is taken from the other parent (takeover parameter)

Mask: **0110011000** (Randomly generated)

Parents: **1010001110**      **0011010010**

Offspring: **0011001010**      **1010010110**

# Crossover operators for real valued GAs

Discrete:

each allele value in offspring  $z$  comes from one of its parents ( $x, y$ ) with equal probability:  
 $z_i = x_i$  or  $y_i$

Could use n-point or uniform

Intermediate

exploits idea of creating children “between” parents (hence a.k.a. *arithmetic recombination*)

$$z_i = \alpha x_i + (1 - \alpha) y_i \quad \text{where } \alpha : 0 \leq \alpha \leq 1.$$

The parameter  $\alpha$  can be:

- constant: uniform arithmetical crossover
- variable (e.g. depend on the age of the population)
- picked at random every time

# Single arithmetic crossover

- Parents:  $\langle x_1, \dots, x_n \rangle$  and  $\langle y_1, \dots, y_n \rangle$
- Pick a single gene ( $k$ ) at random,
- child<sub>1</sub> is:  $\langle x_1, \dots, x_k, \alpha \cdot y_k + (1 - \alpha) \cdot x_k, \dots, x_n \rangle$
- reverse for other child. e.g. with  $\alpha = 0.5$

0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9
-----	-----	-----	-----	-----	-----	-----	-----	-----

0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.5	0.9
-----	-----	-----	-----	-----	-----	-----	-----	-----

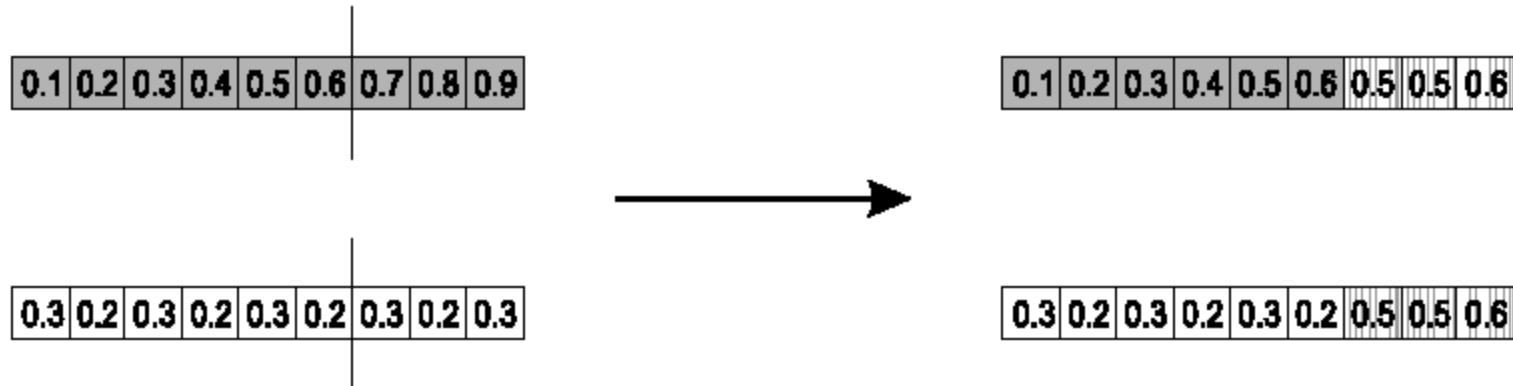

0.3	0.2	0.3	0.2	0.3	0.2	0.3	0.2	0.3
-----	-----	-----	-----	-----	-----	-----	-----	-----

0.3	0.2	0.3	0.2	0.3	0.2	0.3	0.5	0.3
-----	-----	-----	-----	-----	-----	-----	-----	-----

# Simple arithmetic crossover

- Parents:  $\langle x_1, \dots, x_n \rangle$  and  $\langle y_1, \dots, y_n \rangle$
  - Pick random gene ( $k$ ) after this point mix values
  - child<sub>1</sub> is:
- $$\left\langle x_1, \dots, x_k, \alpha \cdot y_{k+1} + (1 - \alpha) \cdot x_{k+1}, \dots, \alpha \cdot y_n + (1 - \alpha) \cdot x_n \right\rangle$$
- reverse for other child. e.g. with  $\alpha = 0.5$

# Whole arithmetic crossover

- Most commonly used
- Parents:  $\langle x_1, \dots, x_n \rangle$  and  $\langle y_1, \dots, y_n \rangle$
- child<sub>1</sub> is:

$$a \cdot \bar{x} + (1 - a) \cdot \bar{y}$$

- reverse for other child. e.g. with  $\alpha = 0.5$

0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9
-----	-----	-----	-----	-----	-----	-----	-----	-----

0.2	0.2	0.3	0.3	0.4	0.4	0.5	0.5	0.6
-----	-----	-----	-----	-----	-----	-----	-----	-----

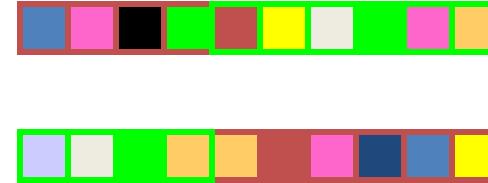

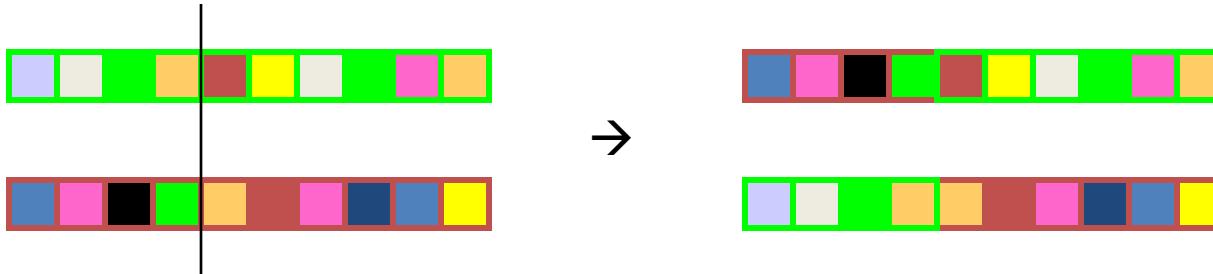

0.3	0.2	0.3	0.2	0.3	0.2	0.3	0.2	0.3
-----	-----	-----	-----	-----	-----	-----	-----	-----

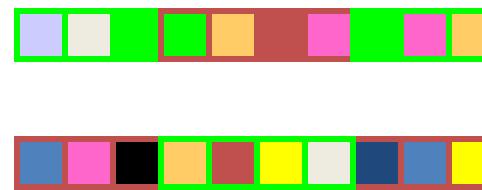

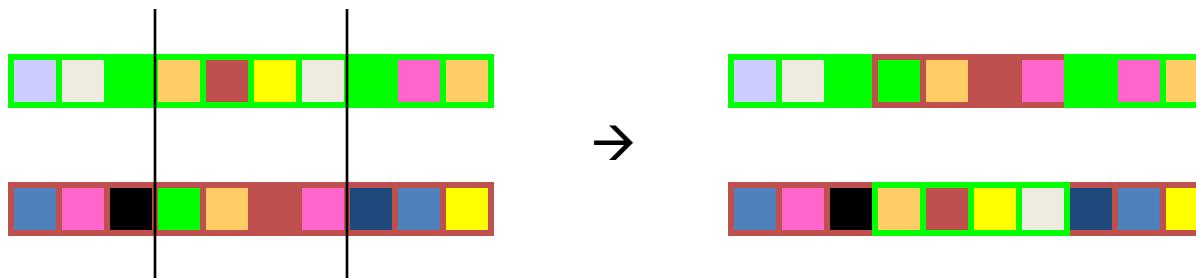

0.2	0.2	0.3	0.3	0.4	0.4	0.5	0.5	0.6
-----	-----	-----	-----	-----	-----	-----	-----	-----

# Crossover comparison

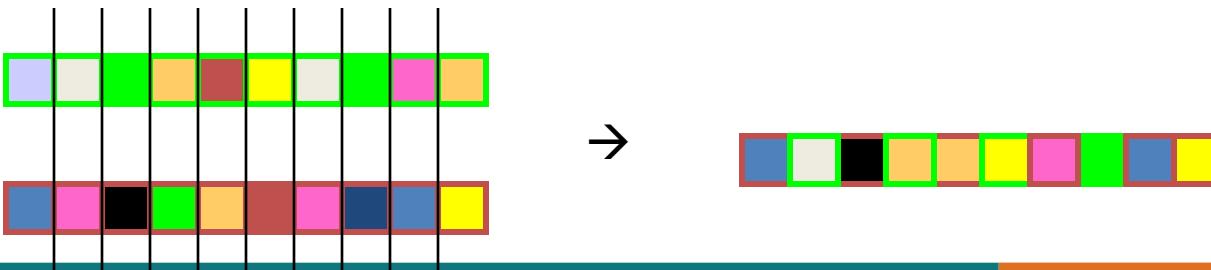

Single point crossover

➊ Two point crossover (Multi point crossover)

➋ Uniform crossover

# Crossover comparison

Is uniform crossover better than single crossover point?

- Trade off between

**Exploration:** Introduction of new combination of features and discover promising areas in the search space, i.e. gaining information on the problem

**Exploitation:** Keep the good features in the existing solution and optimize within a promising area, i.e. using information

# Problems with crossover

Depending on coding, simple crossovers can have high chance to produce illegal offspring

E.g. in TSP with simple binary or path coding, most offspring will be illegal because not all cities will be in the offspring and some cities will be there more than once

Uniform crossover can often be modified to avoid this problem

E.g. in TSP with simple path coding:

Where mask is 1, copy cities from one parent

Where mask is 0, choose the remaining cities in the order of the other parent

# Reproduction Operators

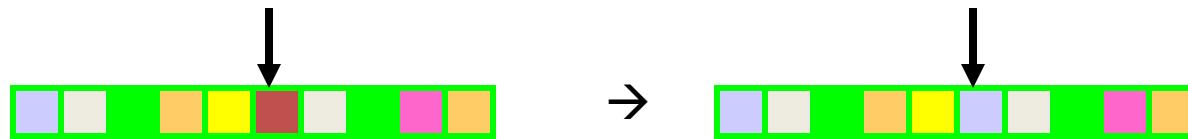

## Mutation

Generating new offspring from single parent

Alter each gene independently with a probability  $p_m$

$p_m$  is called the mutation rate

Typically between  $1/\text{pop\_size}$  and  $1/\text{chromosome\_length}$

Maintaining the diversity of the individuals

Crossover can only explore the combinations of the current gene pool

Mutation can “generate” new genes

# Crossover OR mutation?

Decade long debate: which one is better / necessary / main-background

Answer (at least, rather wide agreement):

it depends on the problem, but

in general, it is good to have both

both have another role

mutation-only is possible, xover-only would not work

# Crossover OR mutation? (cont'd)

There is co-operation AND competition between them

Crossover is explorative, it makes a *big* jump to an area somewhere “in between” two (parent) areas

Mutation is exploitative, it creates random *small* diversions, thereby staying near (in the area of ) the parent

# Crossover OR mutation? (cont'd)

Only crossover can combine information from two parents

Only mutation can introduce new information (alleles)

Crossover does not change the allele frequencies of the population (thought experiment: 50% 0's on first bit in the population, ?% after performing  $n$  crossovers)

To hit the optimum you often need a 'lucky' mutation

# Reproduction Operators

Control parameters: **population size, crossover and mutation probability**

Problem specific

Increase population size

    Increase diversity and computation time for each generation

Increase crossover probability

    Increase the opportunity for recombination but also disruption of good combination

Increase mutation probability

    Closer to randomly search

    Help to introduce new gene or reintroduce the lost gene

Varies the population

Usually using crossover operators to recombine the genes to generate the new population, then using mutation operators on the new population

# Operators: Selection

Main idea: better individuals get higher chance

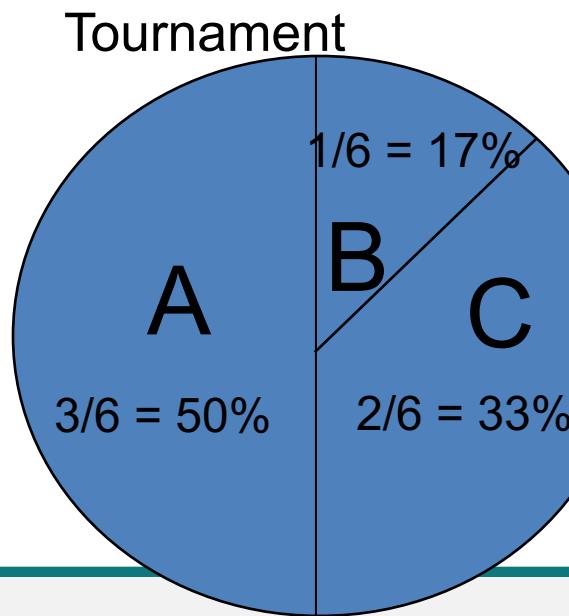

Chances proportional to fitness

Implementation:

Roulette wheel selection (Fitness proportionate selection)

Assign to each individual a part of the roulette wheel

Spin the wheel n times to select n individuals

$$\text{fitness}(A) = 3$$

$$\text{fitness}(B) = 1$$

$$\text{fitness}(C) = 2$$

# Tournament

## Binary tournament

Two individuals are randomly chosen; the fitter of the two is selected as a parent

## Probabilistic binary tournament

Two individuals are randomly chosen; with a chance  $p$ ,  $0.5 < p < 1$ , the fitter of the two is selected as a parent

## Larger tournaments

$n$  individuals are randomly chosen; the fittest one is selected as a parent

By changing  $n$  and/or  $p$ , the GA can be adjusted dynamically

# Fitness Function

## Purpose

Parent selection

Measure for convergence

For Steady state: Selection of individuals to die

Should reflect the value of the chromosome in some “real” way

Next to coding the most critical part of a GA

# A simple example

Suppose your “organisms” are 32-bit computer words

You want a string in which all the bits are ones

Here’s how you can do it:

Create 100 randomly generated computer words

Repeatedly do the following:

Count the 1 bits in each word

Exit if any of the words have all 32 bits set to 1

Keep the ten words that have the most 1s (discard the rest)

From each word, generate 9 new words as follows:

Pick a random bit in the word and change it

Note that this procedure does not guarantee that the next “generation” will have more 1 bits, but it’s likely

# A simple example – GA solution

Suppose your “organisms” are 32-bit computer words, and you want a string in which all the bits are ones

Here’s how you can do it:

Create 100 randomly generated computer words

Repeatedly do the following:

Count the 1 bits in each word

Exit if any of the words have all 32 bits set to 1

Keep the ten words that have the most 1s (discard the rest)

From each word, generate 9 new words as follows:

Choose one of the other words

Take the first half of this word and combine it with the second half of the other word

# The example continued

Half from one, half from the other:

0110 1001 0100 1110 1010 1101 1011 0101  
1101 0100 0101 1010 1011 0100 1010 0101  
-----  
0110 1001 0100 1110 1011 0100 1010 0101

Or we might choose “genes” (bits) randomly:

0110 1001 0100 1110 1010 1101 1011 0101  
1101 0100 0101 1010 1011 0100 1010 0101  
-----  
0100 0101 0100 1010 1010 1100 1011 0101

Or we might consider a “gene” to be a larger unit:

0110 1001 0100 1110 1010 1101 1011 0101  
1101 0100 0101 1010 1011 0100 1010 0101  
-----  
1101 1001 0101 1010 1010 1101 1010 0101

# Comparison of simple examples

In the simple example (trying to get all 1s):

The crossover approach, if it succeeds, is likely to succeed much faster

Because up to half of the bits change each time, not just one bit

However, with no mutation, it may not succeed at all

By pure bad luck, maybe *none* of the first (randomly generated) words have (say) bit 17 set to 1

Then there is no way a 1 could ever occur in this position

Another problem is lack of ***genetic diversity***

Maybe some of the first generation did have bit 17 set to 1, but none of them were selected for the second generation

The best technique *in general* turns out to be crossover with a *small* probability of mutation

# Directed evolution

Notice that, in the previous examples, we formed the child organisms *randomly*

We did not try to choose the “best” genes from each parent

This is how natural (biological) evolution works

Biological evolution is *not directed*—there is no “goal”

Genetic algorithms use biology as *inspiration*, not as a set of rules to be slavishly followed

For trying to get a word of all 1s, there is an obvious measure of a “good” gene

But that’s mostly because it’s a silly example

It’s much harder to detect a “good gene” in the curve-fitting problem, harder still in almost any “real use” of a genetic algorithm

# A realistic example

Suppose you have a large number of  $(x, y)$  data points

For example,  $(1.0, 4.1), (3.1, 9.5), (-5.2, 8.6), \dots$

You would like to fit a polynomial (of up to degree 5) through these data points

That is, you want a formula  $y = ax^5 + bx^4 + cx^3 + dx^2 + ex + f$  that gives you a reasonably good fit to the actual data

Here's the usual way to compute goodness of fit:

Compute the sum of  $(\text{actual } y - \text{predicted } y)^2$  for all the data points

The lowest sum represents the best fit

There are some standard curve fitting techniques, but let's assume you don't know about them

You can use a genetic algorithm to find a “pretty good” solution

# A realistic example

Your formula is  $y = ax^5 + bx^4 + cx^3 + dx^2 + ex + f$

Your “genes” are  $a, b, c, d, e$ , and  $f$

Your “chromosome” is the array  $[a, b, c, d, e, f]$

Your evaluation function for *one* array is:

For every actual data point  $(x, y)$ ,

Compute  $\hat{y} = ax^5 + bx^4 + cx^3 + dx^2 + ex + f$

Find the sum of  $(y - \hat{y})^2$  over all  $x$

The sum is your measure of “badness” (larger numbers are worse)

Example: For  $[0, 0, 0, 2, 3, 5]$  and the data points  $(1, 12)$  and  $(2, 22)$ :

$\hat{y} = 0x^5 + 0x^4 + 0x^3 + 2x^2 + 3x + 5$  is  $2 + 3 + 5 = 10$  when  $x$  is 1

$\hat{y} = 0x^5 + 0x^4 + 0x^3 + 2x^2 + 3x + 5$  is  $8 + 6 + 5 = 19$  when  $x$  is 2

$(12 - 10)^2 + (22 - 19)^2 = 2^2 + 3^2 = 13$

If these are the only two data points, the “badness” of  $[0, 0, 0, 2, 3, 5]$  is 13

# A realistic example

Your algorithm might be as follows:

Create 100 six-element arrays of random numbers

Repeat 500 times (or any other number):

For each of the 100 arrays, compute its badness (using all data points)

Keep the ten best arrays (discard the other 90)

From each array you keep, generate nine new arrays as follows:

Pick a random element of the six

Pick a random floating-point number between 0.0 and 2.0

Multiply the random element of the array by the random floating-point number

After all 500 trials, pick the best array as your final answer

# A realistic example – GA solution

Your formula is  $y = ax^5 + bx^4 + cx^3 + dx^2 + ex + f$

Your “genes” are  $a, b, c, d, e$ , and  $f$

Your “chromosome” is the array  $[a, b, c, d, e, f]$

What’s the best way to combine two chromosomes into one?

You could choose the first half of one and the second half of the other:  $[a, b, c, d, e, f]$

You could choose genes randomly:  $[a, b, c, d, e, f]$

You could compute “gene averages:”

$[(a+a)/2, (b+b)/2, (c+c)/2, (d+d)/2, (e+e)/2, (f+f)/2]$

# Another Example :Travelling Salesman Problem

Problem:

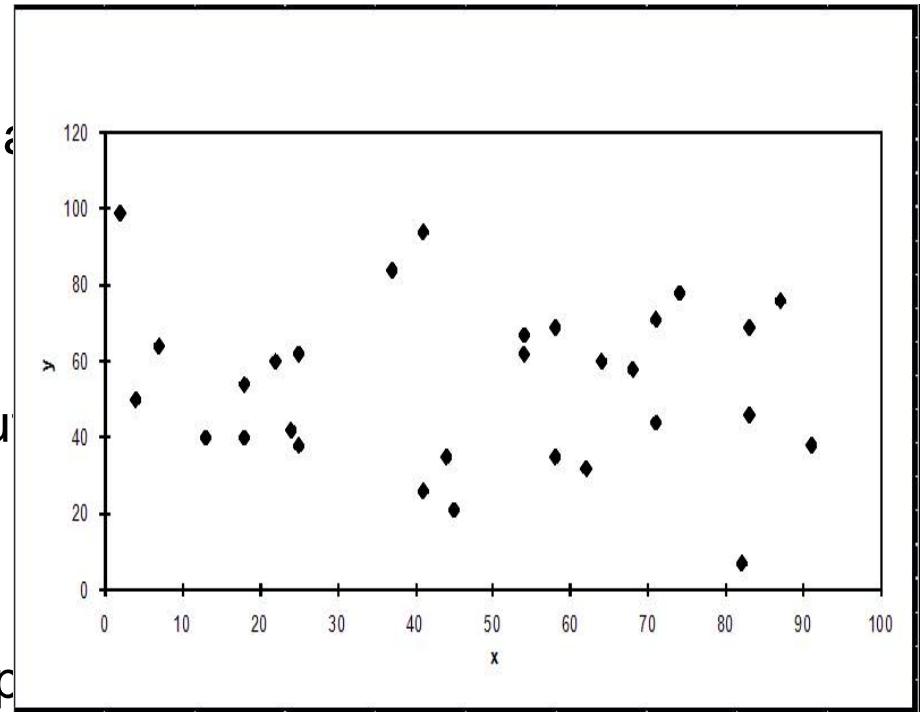

- Given n cities
- Find a complete tour with minimum distance

Encoding:

- Label the cities  $1, 2, \dots, n$
- One complete tour is one permutation of cities (cycles are OK)

Search space is BIG:

for 30 cities there are  $30! \approx 10^{32}$  permutations

# Permutation Representations

Ordering/sequencing problems form a special type

Task is (or can be solved by) arranging some objects in a certain order

Example: sort algorithm: important thing is which elements occur before others (order)

Example: Travelling Salesman Problem (TSP) : important thing is which elements occur next to each other (adjacency)

These problems are generally expressed as a permutation:

if there are  $n$  variables then the representation is as a list of  $n$  integers, each of which occurs exactly once

# Mutation operators for permutations

Normal mutation operators lead to inadmissible solutions

e.g. bit-wise mutation : let gene  $i$  have value  $j$  changing to some other value  $k$  would mean that  $k$  occurred twice and  $j$  no longer occurred

Therefore must change at least two values

Mutation parameter now reflects the probability that some operator is applied once to the whole string, rather than individually in each position

# Insert Mutation for permutations

Pick two allele values at random

Move the second to follow the first, shifting the rest along to accommodate

Note that this preserves most of the order and the adjacent information

1	2	3	4	5	6	7	8	9
---	---	---	---	---	---	---	---	---

1	2	5	3	4	6	7	8	9
---	---	---	---	---	---	---	---	---

# Swap mutation for permutations

Pick two alleles at random and swap their positions

Preserves most of adjacent information (4 links broken), disrupts order more

1	2	3	4	5	6	7	8	9
---	---	---	---	---	---	---	---	---

1	5	3	4	2	6	7	8	9
---	---	---	---	---	---	---	---	---

# Inversion mutation for permutations

Pick two alleles at random and then invert the substring between them.

Preserves most adjacent information (only breaks two links) but disruptive of order information

1	2	3	4	5	6	7	8	9
---	---	---	---	---	---	---	---	---

1	5	4	3	2	6	7	8	9
---	---	---	---	---	---	---	---	---

# Scramble mutation for permutations

Pick a subset of genes at random

Randomly rearrange the alleles in those positions

(note subset does not have to be contiguous)

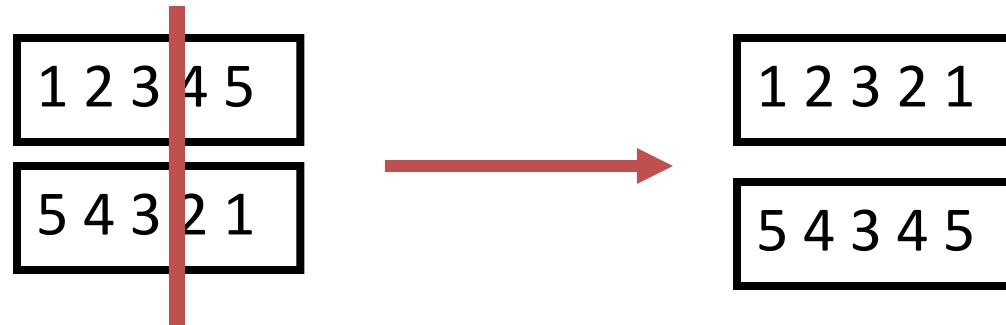

1	2	3	4	5	6	7	8	9
---	---	---	---	---	---	---	---	---

1	3	5	4	2	6	7	8	9
---	---	---	---	---	---	---	---	---

# Crossover operators for permutations

“Normal” crossover operators will often lead to inadmissible solutions

Many specialised operators have been devised which focus on combining order or adjacent information from the two parents

# Order 1 crossover

Idea is to preserve relative order that elements occur

Informal procedure:

1. Choose an arbitrary part from the first parent
2. Copy this part to the first child
3. Copy the numbers that are not in the first part, to the first child:  
starting right from cut point of the copied part,  
using the **order** of the second parent  
and wrapping around at the end
4. Analogous for the second child, with parent roles reversed

# Order 1 crossover example

Copy randomly selected set from first parent

1	2	3	4	5	6	7	8	9
---	---	---	---	---	---	---	---	---

			4	5	6	7		
--	--	--	---	---	---	---	--	--

9	3	7	8	2	6	5	1	4
---	---	---	---	---	---	---	---	---

Rest for the first parent: 1,2,3,8,9

Order for second parent start from right of cut point:

1,4,**9**,3,7,8,2,6,5

Copy rest from first parent follow second parent order 1,9,3,8,2

1	2	3	4	5	6	7	8	9
---	---	---	---	---	---	---	---	---

3	8	2	4	5	6	7	1	9
---	---	---	---	---	---	---	---	---

9	3	7	8	2	6	5	1	4
---	---	---	---	---	---	---	---	---

# Partially Mapped Crossover (PMX)

Informal procedure for parents P1 and P2:

1. Choose random segment and copy it from P1
2. Starting from the first crossover point look for elements in that segment of P2 that have not been copied
3. For each of these  $i$  look in the offspring to see what element  $j$  has been copied in its place from P1
4. Place  $i$  into the position occupied  $j$  in P2, since we know that we will not be putting  $j$  there (as is already in offspring)
5. If the place occupied by  $j$  in P2 has already been filled in the offspring  $k$ , put  $i$  in the position occupied by  $k$  in P2
6. Having dealt with the elements from the crossover segment, the rest of the offspring can be filled from P2.

Second child is created analogously

# PMX example

Step 1

1	2	3	4	5	6	7	8	9
---	---	---	---	---	---	---	---	---

			4	5	6	7		
--	--	--	---	---	---	---	--	--

9	3	7	8	2	6	5	1	4
---	---	---	---	---	---	---	---	---

Step 2

1	2	3	4	5	6	7	8	9
---	---	---	---	---	---	---	---	---

		2	4	5	6	7		8
--	--	---	---	---	---	---	--	---

9	3	7	8	2	6	5	1	4
---	---	---	---	---	---	---	---	---

Step 3

1	2	3	4	5	6	7	8	9
---	---	---	---	---	---	---	---	---

9	3	2	4	5	6	7	1	8
---	---	---	---	---	---	---	---	---

9	3	7	8	2	6	5	1	4
---	---	---	---	---	---	---	---	---

# Cycle crossover

## Basic idea:

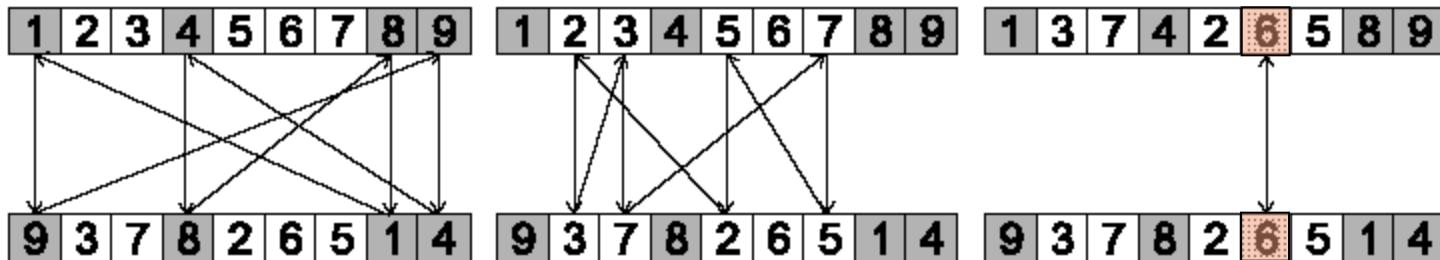

Each allele comes from one parent *together with its position*.

Informal procedure:

1. Make a cycle of alleles from P1 in the following way.
  - (a) Start with the first allele of P1.
  - (b) Look at the allele at the *same position* in P2.
  - (c) Go to the position with the *same allele* in P1.
  - (d) Add this allele to the cycle.
  - (e) Repeat step b through d until you arrive at the first allele of P1.
2. Put the alleles of the cycle in the first child on the positions they have in the first parent.
3. Take next cycle from second parent

# Cycle crossover example

Step 1: identify cycles

Step 2: copy alternate cycles into offspring

1	2	3	4	5	6	7	8	9
---	---	---	---	---	---	---	---	---

1	3	7	4	2	6	5	8	9
---	---	---	---	---	---	---	---	---

9	3	7	8	2	6	5	1	4
---	---	---	---	---	---	---	---	---

9	2	3	8	5	6	7	1	4
---	---	---	---	---	---	---	---	---

# Benefits of Genetic Algorithms

Concept is easy to understand

Modular separate from application

Supports multi-objective optimization

Good for “noisy” environments

Always an answer; answer gets better with time

Inherently parallel; easily distributed

# Benefits of Genetic Algorithms (cont.)

Many ways to speed up and improve a GA-based application as knowledge about problem domain is gained

Easy to exploit previous or alternate solutions

Flexible building blocks for hybrid applications

Substantial history and range of use

# When to Use a GA

Alternate solutions are too slow or overly complicated

Need an exploratory tool to examine new approaches

Problem is similar to one that has already been successfully solved by using a GA

Want to hybridize with an existing solution

Benefits of the GA technology meet key problem requirements

# Some GA Application Types

Domain	Application Types
<b>Control</b>	gas pipeline, pole balancing, missile evasion
<b>Design</b>	semiconductor layout, aircraft design, keyboard configuration, communication networks
<b>Scheduling</b>	manufacturing, facility scheduling, resource allocation
<b>Robotics</b>	trajectory planning
<b>Machine Learning</b>	designing neural networks, improving classification algorithms, classifier systems
<b>Signal Processing</b>	filter design
<b>Game Playing</b>	poker, checkers, prisoner's dilemma
<b>Combinatorial Optimization</b>	set covering, travelling salesman, routing, bin packing, graph colouring and partitioning

# Issues for GA Practitioners

Choosing basic implementation issues:

representation

population size, mutation rate, ...

selection, deletion policies

crossover, mutation operators

Termination Criteria

Performance, scalability

Solution is only as good as the evaluation function  
(often hardest part)
